LIQUID-CRYSTAL DISPLAY HAVING LIQUID-CRYSTAL LAYER ORIENTED  
TO BEND ALIGNMENT

BACKGROUND OF THE INVENTION

5

1. Field of the Invention

The present invention relates to a liquid-crystal display suitable for a wide viewing angle, particularly to a liquid-crystal display having a liquid-crystal layer oriented to bend alignment and suitable for an optically compensated birefringence (OCB) mode.

10 15 20 25 2. Description of the Prior Art

A liquid-crystal display is rapidly spread as a display unit substituted for a CRT because it is thin and a display area can be relatively easily increased.

A liquid-crystal operation mode includes a twisted nematic mode (hereafter referred to as TN mode). The TN mode is realized by rotating the direction of the molecular axis of liquid-crystal molecules (hereafter referred to as director) by approx. 90° between substrates and twist-orienting the liquid-crystal molecules. When applying an electric field vertically to a substrate, a director vertically rotates to display an object.

However, the TN mode has a problem that a viewing angle is narrow. Therefore, it is impossible to visually confirm a displayed object from a diagonal direction.

Moreover, when a screen area is increased, an object is not properly displayed because appearance of the object differs at the center and an end of a screen when viewing the screen from a certain viewpoint in a diagonal direction.

5 To solve the above problem, a viewing angle is expanded by adding a phase compensation plate to a TN-mode liquid-crystal panel in the case of the official gazette of Japanese Patent Laid-Open No. 75116/1994. In the case of this art, however, it is difficult to completely compensate  
10 a twisted structure intrinsic to the TN mode and therefore, the problem is not fundamentally solved yet.

Therefore, OCB (optically compensated birefringence) is noticed as means for improving a viewing angle.

OCB is realized by forming a liquid-crystal layer  
15 oriented to bend an alignment between two substrates and moreover, setting a phase compensation plate for compensating a phase of the liquid-crystal layer outside of each substrate as shown in FIG. 1 to be mentioned later.

A liquid-crystal layer oriented to a bend alignment  
20 represents that liquid-crystal molecules held between two substrates show a symmetric orientation from the center between the substrates as shown in FIG. 4C to be mentioned later. Moreover, directors of liquid-crystal molecules are changed by applying a voltage between the substrates.

25 Moreover, a phase compensation plate having a negative birefringent property is known which is disclosed in the official gazette of Japanese Patent Laid-Open No.

294962/1994. Furthermore, a biaxial phase compensation plate is reported by Kuo et al. in an article titled "Improvement of Gray-Scale Performance of Optically Compensated Birefringence (OCB) Display Mode for AMLCDs" on 5 pp. 927 to 930 of SID'94Digest issued on June 14, 1994.

Furthermore, a hybrid-arranged phase compensation plate having a negative birefringent property is known which is disclosed in the official gazette of Japanese Patent Laid-Open No. 197862/1998.

10 In the case of OCB, when changing directors of liquid-crystal molecules by applying a certain voltage, two types of retardations such as retardation Rlc and phase-compensation-plate retardation Rrf are obtained. When retardation R of the whole OCB obtained by integrating 15 these two types of retardations Rlc and Rrf is equal to zero or a multiple of a wavelength, black is displayed. In the case of a voltage other than the above, white or halftone is displayed.

A liquid-crystal layer oriented to the bend alignment 20 does not include any twist differently from the TN mode. Therefore, phase compensation is easily made and wide-field display is realized.

However, the above conventional OCB has the following problem.

25 That is, in the official gazette of Japanese Patent Laid-Open No. 197862/1998, the product between a birefringent index  $\Delta n$  of a liquid-crystal material in a

cell and a thickness  $d$  of the cell is set to a value between 790 nm and 1190 nm. This value is a value when every liquid-crystal molecule is parallel with a substrate.

When a bend-alignment state is realized, a liquid-crystal molecule at the central portion rises. Therefore, the retardation  $R_{lc}$  of a liquid-crystal layer decreases to about 1/3 to 1/2 of the above value (790 to 1190 nm).

The value of the retardation  $R_{rf}$  of a phase compensation plate is not specified. However, when considering that black display is obtained at a high voltage of approx. 8 V and referring to the value of retardation of a currently-marketed hybrid-aligned negative birefringent phase compensation plate, the retardation  $R_{rf}$  is equal to approx. 100 nm.

In this case, the major axis of the birefringent index of the phase compensation plate is orthogonal to the major axis of the birefringent index of a liquid-crystal molecule. Therefore, the retardation  $R$  of the whole OCB when displaying white becomes approx. 250 to 300 nm. A transmitted-light intensity  $I$  of a liquid-crystal display using the birefringent property can be expressed by the following equation (1),

$$I = A \cdot (\sin(2 \cdot \theta))^2 \cdot (\sin(R \cdot \pi / \lambda))^2 \dots (1)$$

where  $A$  denotes a proportionality factor,  $\theta$  denotes an angle formed between polarization axis and birefringent-index major axis of a polarizing plate, and  $\lambda$  denotes a wavelength of light. From equation (1), it is found that

light having  $\lambda$  of 500 to 600 nm has a high transmittance when setting the retardation R to 250 to 300 nm. That is, setting is made so that light having a green wavelength band is well transmitted.

5 Since a human eye has a high visibility in green wavelength band, brightness rises in the case of the conventional OCB disclosed in the official gazette of Japanese Patent Laid-Open No. 197862/1998.

In the case of the above OCB, however, the following  
10 trouble occurs particularly when performing color display.

Transmittances of red, green, and blue lights when using OCB are shown in FIG. 10 to be mentioned later. That is, transmittances of green and red lights monotonously decrease as an applied voltage rises. However,  
15 transmittance of blue light once increases, peaks at 2.6 V, and thereafter decreases. Therefore, to display gradations, a voltage of 2 to 10 V is applied to red and green lights. However, in the case of blue light, an applied voltage of 2.6 to 10 V must be set differently from the case of green  
20 and red lights.

In the case of a general liquid-crystal display, when applying a voltage to liquid crystal, it is preferable to apply the same voltage to red, green, and blue. This is because, if a different applied voltage is set to each  
25 color, the number of electronic components increases to obtain a desired voltage.

Therefore, to set a proper voltage, the number of

electronic component increases, the manufacturing cost increases, and moreover a circuit substrate increases in size, and thus it is prevented to make a compact liquid-crystal display device.

5

#### SUMMARY OF THE INVENTION

Therefore, it is an object of the present invention to provide a liquid-crystal display making it possible to decrease the manufacturing cost and the size and suitable 10 for the OCB display mode.

In the case of a liquid-crystal display of the present invention, a liquid-crystal layer oriented to bend alignment is set between a pair of substrates and a phase compensation plate for compensating a phase is set outside 15 of each substrate and the retardation of the light passing through the liquid-crystal layer and the phase compensation plate is set so as to be 1/2 or less of the minimum wavelength of the light relating to display.

Moreover, it is possible to set a birefringent index 20 of a liquid-crystal molecule in a liquid-crystal layer to 0.16 or less.

Furthermore, it is possible to set the minimum wavelength of the light relating to display in accordance with a minimum-wavelength color among colors relating to 25 color display.

Furthermore, it is possible to set the minimum wavelength of light in accordance with blue color.

Furthermore, it is possible to set the minimum wavelength of the light relating to display to 380 to 488 nm.

Therefore, in the case of a liquid-crystal display of  
5 the present invention, it is possible to set a liquid-crystal layer oriented to bend alignment between a pair of substrates, set a phase compensation plate for compensating a phase of a liquid-crystal layer outside of each substrate, and set the retardation between the liquid-crystal layer  
10 and the phase compensation plate to a value 1/2 or less of the minimum wavelength of the light relating to display so as to simplify voltage setting relating to display of each color.

15 BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a sectional view showing an embodiment of a liquid-crystal display of the present invention;

FIG. 2 is a top view for explaining the rubbing of substrates shown in FIG. 1;

20 FIG. 3 is a table showing conditions for manufacturing the liquid-crystal display shown in FIG. 1;

FIGs. 4A, 4B, and 4C show orientation states of liquid-crystal molecules of the liquid-crystal display shown in FIG. 1, which are schematic views showing splay  
25 orientation, twist orientation, and bend orientation in order;

FIG. 5 is a characteristic diagram showing calculated

values of state energies of the orientation states shown in FIG. 4;

FIG. 6 is a schematic view showing birefringent properties of the liquid-crystal layer and phase compensation plate shown in FIG. 1;

FIGs. 7A and 7B are schematic views of birefringent properties of the liquid-crystal layer and phase compensation plate shown in FIG. 1 viewed from the front and a diagonal direction;

FIG. 8 is a characteristic diagram showing an electrooptical characteristic of the sample S1 shown in FIG. 3;

FIG. 9 is a characteristic diagram showing an electrooptical characteristic of the sample S2 shown in FIG.

15 3; and

FIG. 10 is a characteristic diagram showing an electrooptical characteristic of the sample S3 shown in FIG. 3.

## 20 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

As shown in FIG. 1, a liquid-crystal display is provided with a pair of substrates 1 and 2 faced to each other. Red, green, and blue color filters 9R, 9G, and 9B are formed on the substrate 1. An overcoat layer 13, a common electrode 10, and a liquid-crystal orientation layer 15 are formed on the color filters 9R, 9G, and 9B.

Pixel electrodes 7R, 7G, and 7B are formed on the

substrate 2. A liquid-crystal orientation layer 16 is formed on the pixel electrodes 7R, 7G, and 7B.

The substrates 1 and 2 are combined so that their liquid-crystal orientation layers 15 and 16 are faced to each other. A liquid-crystal layer 3 is formed between the substrates 1 and 2. Hybrid-aligned phase compensation plates 4 and 5 respectively having a negative birefringent property and polarizing plates 11 and 12 are formed outside of the substrates 1 and 2.

In this embodiment, the pixel electrodes 7R, 7G, and 7B are formed to respectively apply a voltage to each color pixels. Moreover, in the case of a liquid-crystal display having a large display, active matrix driving method can be employed by using active devices such as thin-film transistors.

This type of the liquid-crystal display is manufactured as described below.

First, color filters 9R, 9G, and 9B are formed on a glass substrate 1 through three times of the photolithography steps. In this case, patterning is performed with a material obtained by dispersing red, green, and blue pigments into a polyimide-based photosensitive polymer.

The red color filter 9R uses a filter having the peak of transmittance in 640-nm-wavelength light. The blue color filter 9G uses a filter having the peak of transmittance in 430-nm-wavelength light in order to

improve the light using efficiency together with the peak of the light emitted from a fluorescent tube used as a light source.

When considering a light source and white balance, it  
5 is possible to change each peak wavelength. For example, it is said that a wavelength range of the light judged as blue by a person is 380 to 488 nm, it is preferable to set blue in the above range.

Then, the overcoat layer 13 is formed on the color  
10 filters 9R, 9G, and 9B by spin-coating a polyimide-based transparent polymer and thereafter heating the polymer.

The overcoat layer 13 is used to flatten the irregularity of the color filters 9R, 9G, and 9B and improve the orientation of liquid-crystal molecules. A  
15 material such as polyimide which is not deformed or quality-changed even at 200°C or higher is selected for the color filters 9R, 9G, and 9B and the overcoat layer 13.

Then, an ITO (Indium-Tin-Oxide) film is formed on the overcoat layer 13 by using a sputtering method and which is  
20 patterned to form a common electrode 10.

Then, a liquid-crystal orientation layer 15 is formed by applying polyimide up to a thickness of approx. 50 nm through the use of a printing method, and then subjected to a heat treatment.

25 Moreover, pixel electrodes 7R, 7G, and 7G are formed on the substrate 2 by forming the ITO film and then patterning it similarly to the case of the substrate 1.

Then, a liquid-crystal orientation layer 16 is formed by applying polyimide up to a thickness of approx. 50 nm through the use of a printing method, and then subjected to a heat treatment.

5        Then, rubbing is applied to the substrates 1 and 2 in the directions shown by arrows 101 and 102 in FIG. 2. Polymer beads as spacer beads, each having diameter corresponding to a gap between the substrates 1 and 2, are sprayed on the entire surfaces of either one of the  
10 substrates. Then the both substrates 1 and 2 are arranged to be opposed to each other so that rubbing directions thereof are directed to the same direction.

The substrates 1 and 2 are sandwiched between the hybrid-aligned phase compensation plates 4 and 5  
15 respectively having a negative birefringent property. Moreover, as shown in FIG. 2, tilt directions 201 and 202 of birefringent properties of the phase compensation plates 4 and 5 are made the same as the arrows 101 and 102 showing rubbing directions.

20        The polarizing plates 11 and 12 are bonded onto the phase compensation plates 4 and 5, respectively. The polarization axis of one of the polarizing plates 4 and 5 is set in a direction 301 at an angle of 45° from a liquid-crystal orientation direction. The other of the polarizing  
25 plates 4 and 5 is set in a direction 302 perpendicular to the direction 301.

Three samples S1, S2, and S3 of the liquid-crystal

display thus manufactured are prepared and relations between physical-property parameters of liquid crystal on one hand and an interval between the substrates 1 and 2 on the other when using the samples are shown in FIG. 3.

- 5       The gap between the substrates 1 and 2 is set to 5.5  $\mu\text{m}$ . This is because a birefringent index of liquid crystal currently stably operating at room temperature is equal to approx. 0.16 or less and advantages of the present invention to be described later are effectively shown.
- 10      Physical-property parameters are selected which are almost the same except a birefringent index  $\Delta n$  of liquid crystal so that advantages of the present invention can be easily understood. In this connection, the lower limit of a birefringent index of liquid crystal stably operating at
- 15      room temperature is equal to approx. 0.05 at present.

Then, operations of the liquid-crystal display of this embodiment are described below.

- Because OCB closely relates to an orientation state and an electrooptical characteristic of a liquid-crystal molecule differently from the TN mode, an orientation state of liquid-crystal molecules is first described below.

By applying a voltage between the pixel electrodes 7R, 7G, and 7B on one hand and the common electrode 10 on the other in FIG. 1, directions of a molecular axis of a liquid-crystal molecule, that is, directors are changed. In the case of the liquid-crystal layer 3 formed as described above, orientation states of liquid-crystal

molecules include three states such as splay, twist, and bend states as shown in FIGS. 4A to 4C. State energy of each orientation state depends on the magnitude of a voltage to be applied and the liquid-crystal layer 3 tends  
5 to keep lower state energy.

FIG. 5 shows calculated values of state energies. In the case of three samples S1, S2, and S3 shown in FIG. 3, the state energy of the bend orientation state becomes lower than those of other states when an applied voltage is  
10 2 V or higher. This is the most stable state. In the case of OCB, it is necessary that the liquid-crystal layer 3 is kept in the bend orientation state. Therefore, the samples S1, S2, and S3 can be used in an area having a voltage of 2 V or higher.  
15

Then, electrooptical characteristics of OCB are described below.

OCB is a liquid-crystal mode for displaying an object by controlling the birefringent property. It is assumed that the retardation of the liquid-crystal layer 3 obtained  
20 by applying a certain voltage and changing directors of liquid-crystal molecules is  $R_{lc}$  and the retardation between phase compensation plates 4 and 5 is  $R_{rf}$ . When assuming the retardation of the whole OCB obtained by integrating these two retardations  $R_{lc}$  and  $R_{rf}$  as  $R$ , a transmittance  
25 intensity  $I$  is shown by the above equation (1).

That is, when the retardation  $R$  is equal to zero or a multiple of a wavelength, black is displayed. In the case

of voltages other than the above certain voltage, white or halftone is displayed.

FIG. 6 shows birefringent properties of the liquid-crystal layer 3 and the phase compensation plates 4 and 5.

5 Birefringent properties LC1 to LC5 show birefringent-index ellipsoids of liquid-crystal molecules and birefringent properties RF1 to RF5 show birefringent-index ellipsoids of the phase compensation plates 4 and 5.

Hybrid-aligned negative birefringent properties

10 correspond to birefringent properties of the liquid-crystal layer 3 when black is displayed. The birefringent property LC1 of the liquid-crystal layer 3 correspond to the birefringent property RF1 of the phase compensation plates 4 and 5 and the birefringent properties LC1 and RF1 are compensated each other. Similarly, LC2 and RF2, LC3 and RF3, LC4 and RF4, and LC5 and RF5 are respectively compensated each other.

For example, when observing the birefringent properties LC5 and RF5 from the front, the both properties 20 are orthogonal to each other as shown in FIG 7A. When integrating birefringent indexes of the both properties, an x-directional refractive index nlcx of the birefringent property LC5 becomes equal to a y-directional refractive index nrfy of the birefringent property RF5 and moreover, a 25 y-directional refractive index nlcy of the birefringent property CL5 becomes equal to an x-directional refractive index nrfx of the birefringent property RF5. Therefore,

the retardation R shown by the following equation(2) becomes zero,

$$R = [(n_{LCx} + n_{RFx})/2 - (n_{LCy} + n_{RFy})/2] \cdot d \dots (2)$$

where d denotes a thickness of a liquid-crystal layer.

5        When viewing the birefringent property LC5 and birefringent property RF5 from a diagonal direction along the rubbing direction, the x-directional refractive index  $n_{LCx}$  of the birefringent property LC5 decreases compared to the case of observing the LC5 and RF5 from the front as  
10      shown in FIG. 7B. However, the x-directional refractive index  $n_{RFx}$  of the birefringent property RF5 increases by a value equivalent to the decrease of the x-directional refractive index  $n_{LCx}$  of the birefringent property LC5 and a value obtained by adding the both indexes  $n_{RFx}$  and  $n_{LCx}$   
15      is not changed. Therefore, the retardation R becomes zero.

Similarly, LC2 and RF2, ..., and LC5 and RF5 are respectively compensated each other. Therefore, even when observing OCB from a diagonal direction, the whole retardation R is equal to zero, black can be displayed, and  
20      a wide viewing angle is obtained.

FIG. 8 shows an electrooptical characteristic of the sample S3 in FIG. 3. FIG. 9 shows an electrooptical characteristic of the sample S2 in FIG. 3. FIG. 10 shows an electrooptical characteristic of the sample S3 in FIG. 3.

25        As shown in FIGs. 8 and 9, in the case of the electrooptical characteristics of the samples S1 and S2, transmittances of red, green, and blue monotonously

decrease in an voltage range from 2 V up to a voltage  $V_{b1}$  which is equal to 8 or 9 V at which black display is obtained. However, in the case of the electrooptical characteristic of the sample 3, the transmittance of only  
5 blue does not monotonously decrease but it once increases and then decreases.

The above phenomenon is caused by the following reason.

A transmitted-light intensity is maximized when the retardation  $R$  is equal to  $1/2$  of a light wavelength in  
10 accordance with the above equation (1). This is because, when incident light receives a birefringent property, its phase is shifted by  $\pi$  and thereby, a condition is set that the incident light is directly emitted from an orthogonal polarizing plate.

15 As a result of observing the whole retardation  $R$  of the samples S1, S2, and S3 when applying up to 2 V to  $V_{b1}$ , it is found that the whole retardation  $R$  changes in a range between 142 nm and 0 nm in the case of the sample S1. Moreover, it is found that the retardation  $R$  changes in a  
20 range between 192 nm and 0 nm in the case of the sample S2.

Because transmitted light does not pass through the maximum point of transmitted-light intensity under the above condition, it monotonously decreases. In the case of the sample S3, however, the retardation  $R$  changes in a  
25 range between 262 nm and 0 nm. Transmitted light passes through a point  $R=215$  nm where the transmitted-light intensity of 430-nm-wavelength light is maximized.

Therefore, transmitted light increases up to the point and then, decreases after passing through the point.

Therefore, in the case of the samples S1 and S2 in which the whole retardation R is set to 215 nm or less under operation, transmitted lights of red, green, and blue colors equally decrease to a voltage, it is possible to equalize applied-voltage settings.

In the case of the sample S3, it is impossible to equalize applied-voltage settings because of the above reason when setting an operating voltage to 2 V to Vb1. In this case, the cost increases because it is necessary to increase the number of electronic components for setting applied voltages. However, by setting the operating voltage up to 2.6 V to Vb1, red, green, and blue monotonously decrease and it is possible to equalize applied-voltage settings.

Thus, in the case of this embodiment, it is possible to reduce the manufacturing cost and downsize the display device because of setting the liquid-crystal layer 3 oriented to bend alignment between a pair of substrates 1 and 2, setting the phase compensation plates 4 and 5 for compensating a phase of the liquid-crystal layer 3 outside of the substrates 1 and 2, and setting the retardation R between the liquid-crystal layer 3 and the phase compensation plates 4 and 5 to a value 1/2 or less of the minimum wavelength of light relating to display so as to simplify the voltage setting for displaying each color.

Moreover, this embodiment uses a filter having a transmittance peak in 430-nm-wavelength light as the blue color filter 9B. Moreover, to perform multiple color display, it is permitted to set the whole retardation R to 5 a value 1/2 or less of the light having the minimum wavelength among lights using the whole retardation R under operation. In this case, it is possible to equalize applied-voltage setting for any color.

As described above, according to a liquid-crystal 10 display and its manufacturing method of the present invention, it is possible to reduce the manufacturing cost and downsize the display because of setting a liquid-crystal layer oriented to bend alignment between a pair of substrates, setting a phase compensation plate for 15 compensating a phase of the liquid-crystal layer outside of each substrate, and setting retardations of the liquid-crystal layer and the phase compensation plates to a value 1/2 or less of the minimum wavelength of the light relating to display so as to simplify the voltage setting relating 20 to display of each color.

## WHAT IS CLAIMED IS:

1. A liquid-crystal display comprising: a liquid-crystal layer provided between a pair of substrates so as to be oriented to bend alignment, and a phase compensation plate provided for the outside of each of the substrates, a retardation of a light passing through said liquid-crystal layer and said phase compensation plates being set to a value 1/2 or less of a minimum wavelength of said light relating to display.

10 2. The liquid-crystal display according to claim 1, wherein a birefringent index of a liquid-crystal molecule in said liquid-crystal layer is equal to or less than 0.16.

15 3. The liquid-crystal display according to claim 1, wherein said minimum wavelength is based on a color having said minimum wavelength among colors relating to color display.

4. The liquid-crystal display according to claim 3, wherein said minimum wavelength of said light is based on blue color.

20 5. The liquid-crystal display according to claim 3, wherein said minimum wavelength of said light ranges between 380 nm and 488 nm.

25 6. The liquid-crystal display according to claim 4, wherein said minimum wavelength of said light ranges between 380 nm and 488 nm.

## ABSTRACT OF THE DISCLOSURE

A liquid-crystal display suitable for the optically compensated birefringence (OCB) display mode is used so as to simplify the voltage setting relating to display of each color by setting as follows. A liquid-crystal layer is oriented to bend alignment between a pair of substrates. A phase compensation plate is set for compensating a phase of the liquid-crystal layer outside of each of the substrates. And a retardation between the liquid-crystal and the phase compensation plates is set to a value 1/2 or less of the minimum wavelength of the light relating to display.

Application for United States Patent

**DECLARATION AND POWER OF ATTORNEY**

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name;

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

LIQUID-CRYSTAL DISPLAY HAVING LIQUID-CRYSTAL LAYER ORIENTED TO BEND ALIGNMENT

the specification of which:

(check  
one)  is attached hereto

was filed on \_\_\_\_\_, as  
Application Serial No. \_\_\_\_\_  
and was amended on \_\_\_\_\_.  
(if applicable)

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, § 1.56\*

I hereby claim foreign priority benefits under Title 35, United States Code, § 119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Prior Foreign Application(s)

			priority claimed
<u>69605/1999</u> (Number)	<u>Japan</u> (Country)	<u>16/3/1999</u> (Day/Month/Year Filed)	<u>X</u> yes      no
<u>                </u> (Number)	<u>                </u> (Country)	<u>                </u> (Day/Month/Year Filed)	<u>                </u> yes      no
<u>                </u> (Number)	<u>                </u> (Country)	<u>                </u> (Day/Month/Year Filed)	<u>                </u> yes      no

I hereby claim the benefit under Title 35, United States Code, § 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, § 112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, § 1.56 which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

(Application Serial No.)

(Filing Date)

(Status: patented, pending, abandoned)

**Power of Attorney:** As a named inventor, I hereby appoint Sean M. McGinn, Reg. 34,386, and Frederick W. Gibb, III, Reg. No. 37,629 as attorneys and/or agents to prosecute this application and transact all business in the Patent and Trademark Office connected therewith. All correspondence should be directed to **McGinn & Gibb, P.C., 1701 Clarendon Boulevard, Suite 100, Arlington, Virginia 22209**. Telephone calls should be directed to McGinn & Gibb, P.C. at (703) 294-6699.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful

false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

(An additional sheet(s) is/are attached hereto if the present invention includes more than four inventors.)

\*Title 37, Code of Federal Regulations, § 1.56:

(a) A patent by its very nature is affected with a public interest. The public interest is best served, and the most effective patent examination occurs when, at the time an application is being examined, the Office is aware of and evaluates the teachings of all information material to patentability. Each individual associated with the filing and prosecution of a patent application has a duty of candor and good faith toward the Patent and Trademark Office, which includes a duty to disclose to the Office all information known to that individual to be material to patentability as defined in this section. The duty to disclose information exists with respect to each pending claim until the claim is canceled or withdrawn from consideration, or the application becomes abandoned.

(b) Under this section, information is material to patentability when it is not cumulative to information already of record or being made of record in the application, and (1) it establishes, by itself or in combination with other information, a prima facie case of unpatentability; or (2) it refutes, or is inconsistent with, a position the applicant takes in: (i) opposing an argument of unpatentability relied on by the Office, or (ii) asserting an argument of patentability.
